

Query Parameters

FastAPI Masterclass

Query Parameters

- **Query parameters** are key-value pairs at the end of a route.
- Query parameters allow the client to hit the same endpoint but customize the request.
- A common use case is filtering server records based on or more criteria.

Query Parameter Structure

- Query parameters begin with a **?** at the end of the route followed by one or more key-value pairs.
- The syntax is **key=value**.
- Use an ampersand to separate every two pairs.
 - **?key1=value1&key2=value2**

Example: Reverb.com

- https://reverb.com/holiday?make=gibson&condition=used&price_min=2000&max_price=4000
- The first parameter is **make**, and it has a value of **"Gibson"**.
- The second parameter is **condition**, and it has a value of **used**.

Path Parameters vs. Query Parameters

- FastAPI can distinguish between path parameters and query parameters. A route can use both.
- FastAPI will look for the path parameter in the route string surrounded by curly braces (**{room_id}**).
- FastAPI will assume any other function parameters are query parameters.
- Declare the type annotation to convert the value.
