

Cookies and Headers

Section Review

Cookies and Headers

- A **header** is a key-value pair attached to a request or response. It adds *metadata* (supplemental information).
- A **cookie** is an automated header (**Cookie** name).
- The server asks the browser to store a cookie, and the browser sends it back on subsequent requests to the same domain.

Setting Cookies and Headers on Server

- Use the **set_cookie** method on the **Response** object to ask the browser to save a cookie.
- There is a complementary **response.headers** object where the server can set a header.
 - `response.headers["X-Request-Id"] = "value"`

The Cookie and Header Functions

- Combine FastAPI's **Cookie** or **Header** functions with the **Annotated** type to tell a route handler *where* it should get the value from.
- Rather than defining a function parameter per cookie/header, we can define a Pydantic model to store related fields and perform validation on each one.
